

Replication_{dl}

Luka De Lacey

April 2026

1 Introduction and brief theoretical expectation

This replication paper seeks to replicate that of Krause (2020), who seeks to evaluate the emergence of Radical-Left parties (RLPs) across Europe between the 1990s and late 2010s. He notes cases such as SYRIZA in Greece and Podemos in Spain who saw significant success, particularly in the post-2008 crash era. Given the growing focus in the literature on the emergence of a second dimension focused on cultural issues, Krause (2020) seeks to evaluate how RLPs adjusting their position on both the traditional socio-economic dimension and this new socio-cultural dimension.

Krause's (2020) argument is two-fold. Firstly, that as RLPs moderate on socio-economic issues they grow, while moderation on socio-cultural issues hurts their vote share. Effectively his argument centres on the Downsian (1957) median voter theorem – that as RLPs move in a centripetal manner (i.e. moderate) they encroach on more left-leaning Social Democratic party (SD) voters - thus they grow. He argues this is possible because RLPs have long established themselves on this dimension and are considered 'owning' parts of this dimension - so moderating will likely not impact them. In contrast he expects that they are more likely to move centrifugal on socio-cultural issues primarily because, as he notes, many have taken on the position of issue-entrepreneurs in this space. Effectively by distinguishing themselves from alternative parties, they can appeal to new voters and establish ownership over parts of this dimension.

There comes an additional consideration in his paper where he notes that SDs are likely to react to losses to RLPs by co-opting their positions. Effectively he argues that RLPs are more likely to move in a centrifugal manner if/as SDs position themselves to the libertarian-left, while they are more likely to move in a centripetal manner if SDs are positioned to the economic left. Effectively in the former, RLPs seek to further distinguish themselves from SDs, while in the latter SDs effectively legitimise RLP economic positions.

This paper seeks to build upon previous works (e.g Polacko, 2022, 2023; Bremer, 2023; Abou-Chadi and Wagner, 2024), who argue that Social Democratic parties (SDs) have lost voters to RLPs because of their position on economic issues, in

part during the third-way period of moderation and participation in austerity following the 2008 crash. Effectively, the argument is that SDs lost voters due to this moderation. Works, such as Spoon and Klüver (2019) note that when mainstream parties converge on issues, voters are more likely to move to non-mainstream parties, i.e. RLPs. In this sense 'moderation' is primarily relative. Therefore, this paper argues if SDs moderate their position relative to the largest Mainstream Centre-Right party (MCR), RLPs are expected to benefit. When looking at vote-switching from SDs Abou-Chadi and Wagner (2024) note "about a fifth of former social democratic voters opt for the Radical Left, who oppose social democratic parties mainly on economic issues." (Abou-Chadi and Wagner, 2024, p. 114). Are these SD voters propelling RLPs to success? Interestingly, they argue this is relatively minor to what would be expected if the third-way loss hypothesis were true. Thus this is relatively contested and given the time-frame of the paper, there is some merit to testing it. This sets up hypothesis 1:

H1: A decrease in the logged difference between SD and MCR on economics, the more likely RLPs increase their vote share.

Since Krause (2020) also tests the effect of non-economic, or rather socio-cultural issues, there is some merit to additionally test whether SD moderation on this dimension creates a greater space on their libertarian-left flank which RLPs can win voters on. This sets up hypothesis 2:

H2: A decrease in the logged difference between SD and MCR on economics, the more likely RLPs increase their vote share.

2 Replication

2.1 Data and considerations

The time-frame of the data is 1990 to 2017. With the key outcome variable (OV) being the vote-share achieved by RLPs. An additional lagged vote-share control variable is coded from this OV. This is done because to "... to deal with problems of heteroskedasticity and autocorrelation..." (Krause, 2020, p. 1375). Additionally, "standard errors [are] clustered by election date and party since the error terms are possibly correlated within units and over time." (Krause, 2020, p. 1375). Additionally, party-fixed effects are employed to account for party-specific omitted variables. With the core model of the paper being an OLS regression. This paper employs the same model to allow for comparable results.

A key challenge facing this paper and Krause's (2020) lie in the semi-problematic nature of the Manifesto Project's data. Where a parties position on a given issue can be influenced by exogenous factors, such as manifesto length - which effects the proportion of coded sentences. Additionally, it is noted that unadjusted Manifesto Project data does not account for

$$\begin{aligned}\theta^{(L)} &= \log \frac{R + .5}{L + .5} \\ &= \log(R + .5) - \log(L + .5).\end{aligned}$$

Figure 1: Lowe et al. (2011) log transformation of manifesto data to capture positioning

To mitigate this and still use this valuable data, Krause (2020) follows the formula laid out by Lowe et al., (2011), which creates a log ratio of left-right coded issues. A negative number signifies a greater proportion of left-positioned issues, while a positive number signifies a greater proportion of right-positioned issues.

The core predictor variables are: RLP economic position, RLP socio-cultural position, SD economic position, and SD socio-cultural position. Additional control variables include a percentage turnout variable, a log transformed GDP variable, an unemployment variable, and a Rival RLP variable.

To code for MCR, this paper takes advantage of a previous dataset I have coded to compare how this distance impacts green party vote-share. This dataset is a work in progress, but the MCRs are coded and adjusted for accurately. To create the relevant positional variables, the paper follows the formula of Lowe et al. (2011) as illustrated in Figure 1. Then the difference between the SD and MCR in a given election is coded for.

3 Replication of Krause’s (2020) findings

3.1 Mapping all RLP parties in dataset

Krause (2020) first maps the 210 identified RLPs by their log economic position and log socio-cultural position. This is evident in Figure 1. It illustrates that RLPs largely skew to the left on economic issues - which is expected - and similarly so on socio-cultural issues, though the log-odds ratio is visibly smaller here.

Figure 2: Economic and non-economic positions of West European radical left parties, 1990–2018.

3.2 Summary statistics

Table 1 illustrates the key summary statistics of all variables. I have additionally coded my logged Main Centre-right party socio-economic and socio-cultural positioning with a mean position of log 0.605 on economics and log 0.114 on culture. The key PVs of this replication are additionally coded - on socio-economics, SDs and MCRs differ by log 1.014, while on socio-cultural issues they differ by log 1.089.

Table 1:

Statistic	N	Mean	St. Dev.	Min	Max
rl.v_share_wgt	120	0.081	0.072	0.004	0.363
rl.v_share_wgt_l	120	0.077	0.071	0.000	0.363

sd_mcr_diffc	120	1.089	0.855	0.059	4.219

3.3 Regression results of Krause (2020)

Table 1 illustrates the results from Krause’s (2020) models. The results seemingly largely align with three of his hypotheses. That centripetal movement on cultural issues is on average associated with a decrease in RLP vote share by 0.005. This finding is statistically significant. Additionally there is credence for the argument that centripetal movement on economic issues helps RLPs, with a log unit increase in position (noting that a negative position is more left) associated with an average increase by 0.015.

Similar negative effects are visible for when RLPs are in government, not in government, supporting the government (though this is not statistically significant), and especially so when they have a RLP challenger (associated with an average decrease of 0.291)

Interestingly the statistical significance of the logged GDP coefficient suggests that an increase in one logged unit of GDP is on average associated with an increase in RLP vote share holding all else constant. Krause (2020) notes previous works which indicate a growth in GDP is associated with an increase in inequality, benefitting RLPs – due to their association with addressing it.

3.4 Illustrating marginal effect of economic moderation

Figure 3 seeks to further illustrate hypothesis three of Krause (2020) - that the centripetal effect of RLP economic position is conditioned by SD economic position. This suggests, as Krause (2020) does, that the success of RLP moderation necessitates competition on the economic left.

3.5 Modelling for MCR-SD ideological differences

Next I followed the same format as Krause (2020) to construct my models. They employ the same control variables with minor model specific adjustments.

Figure 3: Marginal effect of RLPs' economic positions conditional on MLPs' economic positions, with 95 percent confidence interval.

Model 3 and 4 do not incorporate the SD economic/cultural position variables to account for potential issues with multicollinearity. While models 1 and 3 incorporate additional interaction variables.

Despite expectations of this paper's hypotheses, the log distance between the SD and MCR is, on average, not clearly associated with an increase/decrease on the vote share received by the RLP. There is a marginally statistically significant finding, that, on average, the increase in log distance between the SD and MCR parties on socio-cultural issues is associated with an increase in RLP vote share of 0.005 or effectively 0.5 percent, when all else is held constant. However, the p-value is still greater than 0.05. Therefore we cannot reject the null hypotheses.
